Alcohol, Tobacco, and Other Drug Use by Indiana Children and Adolescents The Indiana Prevention Resource Center Survey - 2003

Executive Summary and Highlights

Data from the 2003 survey indicate that for the most part, illicit drug use by Indiana children and adolescents is still on the decline. The period from the early to mid-1990s saw dramatic increases in drug use among youth, peaking in 1996. Subsequent tracking of illicit drug use by youth indicate a **slow but steady decline for most drugs and among most age groups.**

The most notable decreases are in tobacco prevalence rates. Indeed, cigarette smoking rates among youth decreased for all grades except 6th. In many cases, the decline in youth smoking prevalence is dramatic (i.e., 5 percentage points). Among 7th, 8th and 9th graders, cigarette use is less than one-half of those rates reported in 1996. Prevalence rates for other tobacco products (e.g., smokeless tobacco, cigars) also show a decrease for most ages.

This year's survey is the thirteenth annual survey coordinated by the Indiana Prevention Resource Center (IPRC) at Indiana University, and was funded by the Indiana Family and Social Services Administration, Division of Mental Health and Addiction. The survey's findings are based upon analysis of data from 156 separate local surveys of 141,342 youth in grades six through twelve, attending 450 schools in Indiana.

Although use of marijuana and most other "illicit drugs" has declined over the past five years, **rates of marijuana and most other "illicit drug" use continue to be substantially higher than the rates reported in 1992.**

National data showed a steady decrease in use rates for other drugs from about 1980 through 1992, followed by sharp increases from 1993 to 1997. The data from 1998 National surveys showed a leveling of the increases, followed by a slight decrease beginning in data from 1999 through 2002. National survey data for 2003 will not be available until late December.

Statewide survey results strongly suggest that prevention initiatives are working in Indiana, and are being sustained over time. Statewide prevention initiatives have been in place for more than 7 years, and include 390 after-school prevention programs. In addition, along with other coordinated statewide prevention efforts, federal mass media campaigns aimed at reducing drug use among youth are still in effect. These efforts, combined with continuing changes in policies and public attitudes about tobacco use, appear to be changing the social norms pertaining to tobacco use among youth. In fact, most drug use by Hoosier children and adolescents declined dramatically over the past six years. The changes are most noticeable among 7th, 8th, and 9th graders -- the three grades targeted by statewide prevention initiatives. Further, these targeted cohorts appear to be maintaining the changes as they become older. The 12th graders use fewer drugs and at a lower rate than 12th graders from five years ago. For some drugs, Indiana rates have finally fallen below National rates. This year's most significant findings follow.

“Club Drugs” Data for the Second Year

This year’s survey was the second in this series to include questions on “club drugs.” “Club drugs” is a term used to describe the drugs ecstasy (MDMA, 3,4-methylenedioxy methamphetamine), GHB (gamma hydroxy butyrate), and Rohypnol (flunitrazepam), which are commonly associated with techno dance clubs and “raves.” GHB and Rohypnol have also been called “date-rape drugs” since they can incapacitate an unsuspecting person who unknowingly takes the drug, making them vulnerable to non-consensual sexual activities. Ecstasy is a mild hallucinogenic drug that users claim “enhances the intensity of techno music effects.” All three drugs have been associated with serious injury and death. Club drugs have become increasingly popular among college students and other young adults. Since 2000, there has been a dramatic increase in the number of police encounters with club drugs, thus the IPRC survey was modified to determine the extent to which adolescents are now using these drugs.

Use of Rohypnol among middle school students is higher (approximately 1.5% lifetime prevalence) than GHB use (approximately .5%) among the same age group. Similar to the previous year, use of these drugs by high school students is approximately 1.5% for lifetime prevalence (i.e., using once in their lifetime). For the most part, Indiana data for these substances are consistent with national surveys reported elsewhere. Use of ecstasy for sixth graders is minimal, but doubles to 1.8% by seventh grade. Lifetime use by older adolescents in high school dropped in 2003 as compared to 2002 use rates. Approximately 1.7% of students in grades 10 -12 reported use of MDMA on a regular basis (one or more times each month), which is lower than 2002 reported rates.

Last year’s findings suggest that ecstasy use is age dependent, in that it was more common among older adolescents who were nearing college age. While two years worth of data is insufficient for establishing a trend, this year’s findings support the notion that club drug use may be more prevalent among those who have access (i.e., may be more likely to be admitted to dance clubs and parties where these drugs are more readily available). However, the rising rates among younger adolescents should be closely watched and may suggest an area of potential programmatic need.

Youthful Tobacco Use Continues to Drop

Indiana tobacco use rates among youth continue to decline. Indeed, lifetime cigarette use among 10th and 12th graders has dropped below National rates for the first time. For most grade levels, the decline in tobacco use has been and continues to be strong – at times as much as 3 percentage points. While on the decline, use of other tobacco types of products use among Indiana youth still remain above the National averages.

Retailer compliance with tobacco sale laws to minors continues to be monitored by two parallel initiatives (the Synar Amendment and the Tobacco Retailer Inspection Program). Some of the observed decreases in rates reported over the past three years can be attributed to these initiatives, which were designed to increase retailer compliance with restricting access by youth to tobacco products. These efforts have made impact on cigarette prevalence rates, as decreases are reported for most grades.

The 2000 census reports indicate approximately 605,000 Indiana youth are of ages 11 through 17 years. Using these figures and comparing 2003 rates to 1996 rates, current data indicate that about 73,800 fewer Indiana children and adolescents smoke cigarettes on a monthly or more frequent basis than before. Furthermore, about 51,200 fewer Hoosier youth smoke cigarettes daily, and about 36,400 fewer smoked a half pack or more per day.

Monthly Cigarette Use				Daily Cigarette Use			
Year	1996	2003	Change	Year	1996	2003	Change
6 th	9.70%	5.10%	-4.60%	6 th	4.20%	2.20%	-2.00%
7 th	19.00%	8.10%	-10.90%	7 th	10.40%	3.60%	-6.80%
8 th	27.10%	14.00%	-13.10%	8 th	15.40%	7.20%	-8.20%
9 th	34.40%	17.90%	-16.50%	9 th	22.20%	10.30%	-11.90%
10 th	36.70%	22.20%	-14.50%	10 th	24.40%	13.70%	-10.70%
11 th	40.10%	25.20%	-14.90%	11 th	27.30%	16.00%	-11.30%
12 th	39.80%	28.80%	-11.00%	12 th	27.00%	18.70%	-8.30%
AVG.	29.54%	17.33%	-12.21%	AVG.	18.70%	10.24%	-8.46%

Daily Half-Pack+ Cigarette Use			
Year	1996	2003	Change
6 th	2.10%	0.80%	-1.30%
7 th	5.70%	1.70%	-4.00%
8 th	8.80%	3.70%	-5.10%
9 th	14.00%	6.10%	-7.90%
10 th	16.20%	8.10%	-8.10%
11 th	18.90%	9.90%	-9.00%
12 th	18.60%	11.90%	-6.70%
AVG.	12.04%	6.03%	-6.01%

The decreases in tobacco use were almost universal. Cigarette smoking and smokeless tobacco use decreased for all grades except 6th grade on nearly all measures of prevalence: lifetime, annual, monthly, and daily.

Cigarette smoking has been shown to be a "gateway drug" that can lead to the use of other drugs. Smoking rates are the best statistical predictor of other types of drug use by children and adolescents. In fact, the decision to use tobacco is such a powerful statistical predictor of future decisions to use other drugs that evidence indicates youth smokers are 10 to 50 times more likely than nonsmokers to use marijuana, cocaine, and other illicit drugs. This relationship was first reported in 1992 (Torabi, Bailey & Majd-Jabbari, 1992). The strength of this relationship strongly suggests that decreases in tobacco use should lead to future decreases in the use of other drugs.

General Reduction in Alcohol Use Rates This Year

As reported in the 2002 report, the decline in Indiana adolescent alcohol use has been slow and inconsistent. However, results for the 2003 report (as compared with 1991) show significant decreases in most prevalence measurements and for most grades for alcohol use. The exception is among 6th graders, where significant increases are found for annual and monthly prevalence. There were decreases in occasional use, particularly among higher grades. In fact, binge drinking rates for 10th grade fell below reported National rates. However, heavier and more frequent drinking patterns remained steady. Similar to what was reported the previous year, while youth appear to be experimenting less with alcohol, youth who drink regularly (daily) did not change much as compared to 2002.

Reported rates of “binge drinking” (i.e., drinking five or more drinks on a single occasion) declined dramatically in 2001, but steadied in 2002. It was considered that the decline might be due, in part, to a redesign of the survey questionnaire in 2001 which resulted than a higher-than-usual “no answer” rate for the binge drinking question. Due to a slight redesign in the format of the survey questionnaire, the binge drinking question was placed in a different location on the 2002 and 2003 surveys. The “no answer” rates were comparable for 2002 and 2003 (approximately 13.6%), but still higher than previous years (approximately 11.5%). It would be expected that a drop in binge drinking would be accompanied by a similar drop in monthly drinking. While most grades show signs of a slight decline, none were statistically significant. Essentially, monthly alcohol use rates among youth remain steady, albeit higher than National rates, although this finding should be interpreted with caution. As stated in the 2001 report, analysis of results over several years will be needed before we can conclude that the decrease is real.

		YEAR	
		2002	2003
Binge Drinking	No Answer	10437 13.5%	19388 13.7%
	None	54476 70.7%	99246 70.2%
	Once	5064 6.6%	9218 6.5%
	Twice	2909 3.8%	5470 3.9%
	3-5 times	2581 3.3%	4871 3.4%
	6-9 times	761 1.0%	1465 1.0%
	10+ times	840 1.1%	1684 1.2%
	Total	77068 100%	141342 100%

Indiana Drug Use Rates Similar to National Rates

Throughout the 1990s, the rates of use by Hoosier youth for almost all drugs exceeded the rates reported in national surveys -- often significantly. But recently, the variance between Indiana and national rates has narrowed significantly -- especially among younger youth. By 2000, the Indiana rates for marijuana, cocaine, crack, heroin, and steroids were near or below the national rates for most grades and measures of prevalence. Indeed, most prevalence rates among Indiana 12th grade youth are lower than state rates.

“Cohort Effect” for Year-to-Year Comparisons

Use of cocaine, prescription drugs, and similar illicit drugs use rates was approximately the same as reported in 2002. However, inhalant use shows some sign of increase among younger adolescents (i.e., 6th through 8th grades). There were no increases in similar drug use among older adolescents (i.e., 11th and 12th grades) and at all prevalence levels.

In our 1997 report, we noted that drug use by youth in the class of 2002 was substantially lower than would have been predicted by examining use rates of other classes. This class or “cohort” was in 6th grade at the time, but have now since graduated and were not included in the 2003 survey. As this class matured through middle and high school, they continued to report somewhat lower than predicted use rates. National surveys have identified occasional cohorts that had either higher or lower than average use rates in middle school and these characteristics followed them throughout their educational careers. This so-called "cohort effect" may influence our interpretation of data for adjacent classes, particularly the class that follows them.

The prevalence rates for several drugs among Indiana youth in 6th grade suggest that another cohort effect might be present. Prevalence rates for this cohort appear to be on the increase, as compared to 6th grade youth from previous years. Indeed, among this group, inhalant use showed significant increases as compared to 2002 and for all prevalence levels. This cohort should be closely followed during the upcoming years in order to ascertain if a true cohort effect exists. If so, these increases in drug use rates for youth at this young age strongly suggest the need for realignment of prevention efforts.

INTRODUCTION

This report describes the main findings from the thirteenth annual survey of alcohol, tobacco, and other drug use by Indiana children and adolescents coordinated by the Indiana Prevention Resource Center under a contract with the Indiana Family and Social Services Administration - Division of Mental Health and Addiction (formerly the Indiana Department of Mental Health, Division of Addiction Services). This survey provides information about the prevalence of alcohol, tobacco, and other drug (ATOD) use needed for statewide and local planning purposes. From mid-March to mid-April, 2003, data were collected by local school officials in local surveys in 450 schools in 156 different communities in Indiana. The Indiana Prevention Resource Center (IPRC) coordinates statewide analysis of these separate data sets for its annual "Alcohol, Tobacco and Other Drug Use Survey," to provide a scientifically designed, weighted, representative sample of the statewide prevalence of ATOD use by children and adolescents in Indiana.

The survey was designed with two purposes in mind: (1) to measure ATOD prevalence on a statewide basis for statewide planning and evaluation, and (2) to measure ATOD prevalence on a local basis for local planning and evaluation purposes. Since detailed information is required by many local communities in order to qualify for federal or state funding, a very large number of schools volunteer to participate in the IPRC's survey. Although other survey instruments are available to local schools, the IPRC survey and its reports are provided to the local communities without charge. Widespread participation in the survey generates a statewide sample that is much larger than would be needed simply for statewide planning purposes, but is necessary in order to generate meaningful community-level data. Most participating schools are scheduled to participate on a biennial or triennial basis, but the state's largest school district (with about 8% of the total state school population), among others, now participates annually to avoid skewing the "off-year" results.

For 2003, data were collected in 156 separate communities or school corporations; surveys were conducted in 450 schools throughout Indiana. This yielded 141,342 usable surveys. The school surveys conducted this year provided enough data from which to draw inferences about alcohol and other drug use by students in grades 6 through 12 throughout the entire state. Indeed, the ATOD Survey has an established record of obtaining such samples.

Year	Number of Usable Surveys	Year	Number of Usable Surveys	Year	Number of Usable Surveys
1991	23,319	1996	36,586	2001	89,861
1992	20,269	1997	72,571	2002	77,068
1993	90,586	1998	44,232	2003	141,342
1994	81,732	1999	81,685		
1995	63,631	2000	72,523		

The 1991 through 1993 surveys included fifth graders, who were eliminated in 1994. The fifth grade samples were more difficult to obtain, required working with many more elementary schools, and were much less reliable due to a disproportionate number of unusable surveys. Since data on fifth graders were not required for statewide planning purposes, they were eliminated from future samples. As data are reported by grade, elimination of fifth graders does not influence the prevalence rates in grades 6 through 12. While identical populations were not sampled each year, the populations are comparable, and were selected for geographic and community-size balance in an identical manner, and thus, should produce comparable data.

An attempt was made to assure geographic and community-size balance, with an appropriate number of schools and subjects selected from each region of the state, as well as appropriate sized rural, urban, and minority populations. The communities selected for participation are representative of the state in terms of rural/urban and ethnic mix.

Schools are selected in a three-stage purposive stratified sampling process to yield a sample that is representative of the state as a whole. A three-stage purposive/quota cluster sampling procedure is used to yield a representative sample of Indiana students that are stratified by grade and purposively selected taking into account geographic balance, ethnic diversity, and community size. Schools and communities are purposively selected to assure proportional representation from the various parts of the state, utilizing ten planning regions established by the Governor's Commission for a Drug-Free Indiana, and to assure adequate sampling of minority populations and of students from rural areas. Schools then are assigned a quota designed to yield appropriate numbers of participants in each grade.

Intact classes are randomly selected as sampling clusters. The sample represents the sociodemographic makeup of the state reasonably well, based upon the 2000 Census of Population and Housing. The 2003 sample consisted of appropriate subsamples from each of the ten planning regions. The number of African-American respondents and Hispanic respondents appropriately represented their share of the state's population. Although not true random sampling, the sampling procedure used in this study is comparable to that used in the National High School Survey (Monitoring the Future study) (Johnston, O'Malley and Bachman, 2002), and its massive size (more than 77,000 participants) and representativeness make it a valuable and reliable sample of the population.

Given the changing demographics of the state, the sampling size was increased for the 2003 year for the following reasons: (1) It improves the likelihood of inclusion for certain sub-populations (e.g., Hispanic/Latino) who have growing and increased presence in Indiana, and (2) it allows for an assessment to be made of the comparability and validity of the original sampling method. In other words, one can determine whether the original method with a smaller sample is truly and adequately reflective of the state's youth (including growing subpopulations). Tests of similarities and representation on the 2003 sample provided evidence that the original sampling method with the smaller sample size is appropriate.

Youth Surveys	450 schools in
	156 separate community or school corporation surveys

Total Population Present on Day of Survey	151,398
No grade reported	1,347
Unusable Surveys/Refused to Participate	3,976
Surveys Rejected Due to Error Checking	4,733
Total Number of Usable Surveys	141,342
Participation Rate (Usable Surveys/Total Population)	93.4%

Number of Youth Respondents	141,342
6th grade	23,382
7th grade	19,681
8th grade	26,935
9th grade	19,487
10th grade	21,760
11th grade	14,597
12th grade	15,500

Gender Distribution		
Male	69,301	49.0%
Female	71,667	50.7%
No response	374	0.3%

The anonymous written questionnaire was selected for reasons of data quality, cost and time efficiency and effectiveness, as well as prior experience. Self-administered written questionnaires "were found to produce more complete reporting of drug use... [particularly] for reporting of more recent use of 'harder' drugs" (Schober, Fe Casa, Pergamit & Branden, 1992). This method is comparatively less expensive than other data collection methods, and is feasible with school-aged youth, given the relatively easy access to this population through administration in school settings. With Indiana's relatively strict enforcement of mandatory school attendance laws, more than 98% of the youth population under age 16 may effectively be reached through school-administered surveys. School drop-out is a significant problem after age 16, and these data reflect only **those students still in school**. Johnston, *et al.*, (1993) describe a protocol that can be used to estimate the total prevalence (including the drop-out population) from data such as these.

DEFINITIONS

Prevalence: the rate of "total cases" of a health issue. Prevalence rates of drug use are traditionally reported as percentages of all drug use over a particular time frame in the entire population at risk. This survey uses several different measures of prevalence.

Lifetime prevalence: the percentage of respondents in an entire grade or age group that reports using a particular drug at least once in their lifetime.

Annual prevalence: the percentage of respondents in an entire grade or age group that reports using a particular drug at least once during the year prior to the administration of the survey.

Current Use or Monthly prevalence: the percentage of respondents in an entire grade or age group that reports using a particular drug at least once in the 30 days prior to the administration of the survey.

Binge drinking: the percentage of respondents in an entire grade or age group that reports drinking at least five alcoholic drinks at a sitting (approximately the amount needed to raise a person's blood alcohol level to about 0.08%) in the 2 weeks prior to administration of the survey.

Daily prevalence: the percentage of respondents in an entire grade or age group that reports using a particular drug an average of once per day during the 30 day period prior to the administration of the survey. [This rate is inferred from the frequency response to a question about monthly prevalence, which is the same technique used in the two national surveys used for comparison purposes.]

PURPOSE AND RATIONALE

This survey was funded by the Indiana Family and Social Services Administration, Division of Mental Health and Addiction, in order to provide a means of meeting the needs of both state and local alcohol and other drug prevention and treatment professionals for information regarding the prevalence of alcohol, tobacco, and other drug use among the youth population of Indiana. There are several needs of both community and state that are met by this survey. For example, this survey allows Indiana to meet federally mandated guidelines for the allocation and expenditures of funds for drug abuse programs. The most efficient allocation of resources requires accurate information about the extent of alcohol and other drug use.

An accurate assessment of local needs is also a major step in designing and implementing alcohol, tobacco and other drug programs for individual communities. This survey allows local professionals to assess the need for programs, and to meet the requirements of funding agencies for an accurate assessment of the extent of the local need. An accurate and comprehensive cross-sectional survey of the prevalence of alcohol, tobacco and other drug use had not recently been conducted in Indiana, prior to the IPRC's 1991 survey. The studies that had been conducted were largely independent, localized efforts that yielded specific information about individual communities. Some of these studies were not conducted by qualified survey researchers, nor were the instruments tested for validity and reliability. Other studies were conducted by private organizations, often at great expense to the community.

This survey began a useful statewide database of information about the prevalence of alcohol, tobacco, and other drug use in Indiana. The individual surveys conducted as a part of this survey provide local communities with specific information needed by them to assess local needs. Since all of the local surveys were conducted using the same protocol and same instrument, and because these protocols and instruments yield data that is directly comparable to two major national surveys, valid comparisons can be made and reasoned inferences can be drawn from those comparisons.

METHODOLOGY

The survey instrument is a four-page self-contained questionnaire developed by the Indiana Prevention Resource Center in 1991. Items are based upon the questionnaires developed for the National Household Survey on Drug Abuse (NIDA, 1991) and for the National Institute on Drug Abuse's "Monitoring the Future" National High School Survey (Johnston, *et al.*, 1991, 1992, & 1993), and all of the drug use-related items on the questionnaire are directly comparable to items on the national surveys. Items were selected for their value in providing statewide planning data and for comparability with national data. Items were originally constructed to yield data to measure progress toward meeting the national health objectives set out in *Healthy People 2000*.

All of the items were closed-ended questions, including three demographic questions, an eight-digit school code that provides geographic information, and a series of Likert-type items, arranged in subscales, to measure:

- the prevalence of cigarette smoking,
- the prevalence of alcohol, smokeless tobacco, and other drug use,
- adverse consequences due to alcohol and other drug use experienced by the respondent students,
- perceived risks of using alcohol and other drugs, and
- perceived peer approval/disapproval of the student's alcohol and other drug use.

In 1995, additional subscales were added to measure:

- perceived alcohol and other drug treatment needs for children and adolescents in Indiana,
- safety concerns, violence, and weapons use, and
- participation in structured and unstructured recreational and informal educational activities.

In 1998, the following modifications were made:

- questions on cigar smoking, pipe smoking, non-medical use of Ritalin, and use of methcathinone were added to all of the prevalence subscales,
- the subscales on school violence were altered slightly to conform with new U.S. Department of Education data collection guidelines,
- the subscale on recreational and informal educational activities was revised substantially.

In 2002, the following modifications were made:

- questions on lysergic acid diethylamide (LSD), methylenedioxy methamphetamine (MDMA, ecstasy), flunitrazepam (Rohypnol, roofies), and gamma hydroxy butyric acid (GHB) were added to all of the prevalence subscales.
- questions assessing psychedelic prevalence were modified to be more specific (i.e., LSD Only, and Other Psychedelics).

This report describes only the responses to the alcohol, tobacco, and other drug use prevalence questions. Additional monographs in this series will report on the treatment needs; safety, violence, and weapons use; and participation in youth activities questions.

The questionnaire was designed to offer consistency of measurements over time, provide statistics that were comparable to nationally-conducted drug use surveys, and for ease of use and simplicity. Therefore, the results can be plainly presented in an easily understood format, and the results from Indiana can be compared with those from national surveys. The questionnaire is intended for use over several samplings. There are several benefits to this strategy:

First, it provides for the construction of a large database. The larger a database, the more inherently accurate and valid the collected data will be.

Second, the more accurate the Indiana data are, the more accurate the comparisons between Indiana data and other national data become (as the national surveys have collected data from tens of thousands of subjects).

Third, since the data are comparable both through the structure of the questionnaire and the times the questionnaires are administered, any changes will more accurately reflect actual changes in the use of the drugs examined. These changes can reflect upon various prevention strategies, through pre- and post-testing. For example, if the survey were administered at a school before that school begins a new prevention program and then surveyed again after the program has been implemented, then subsequent changes in the results of the two surveys can better be attributed to that program.

During development of the survey, the basic questionnaire was reviewed by a panel of experts for content validity, subjected to 6 months of pilot testing and reviewed by focus groups of school-aged youth, and tested for reliability using the test-retest method (correlation coefficient 0.82). A SMOG Index of Readability was calculated to assure readability at the 5th grade level. The survey form is optically scannable, allowing for direct transfer of data from the forms to a computer file, utilizing an NCS Op-Scan 8 reader. The collected data are analyzed using descriptive statistical techniques, and multiple regression through SPSS-PC routines operating in a WindowsXP environment on a high end Pentium IV platform, or in a HP-UX environment on large DEC-Alpha mainframes.

The questionnaire used in this survey was designed by the Indiana Prevention Resource Center for use in school settings. All of the questions are comparable to both the National High School Survey (conducted by the University of Michigan) and the National Household Survey (conducted by the National Institute on Drug Abuse), which show drug use rates for high school 8th, 10th and 12th graders, and for persons aged 12 and over, respectively.

The basic portion of each questionnaire is divided into sixteen multi-part questions. [See Appendix for copy of the questionnaire.] For the original instrument, items were selected to gather data comparable to the *Healthy People 2000* standards utilized by the U.S. Public Health Service, with the intention of producing data that could be used to assess the state's and a community's success at meeting the *Healthy People 2000* target goals. *Healthy People 2010* serves as the current planning document. Since these goals often are the basis for evaluation specified in federal and state grant funding announcements, the data will assist Indiana applicants in securing such funding.

As in the previous twelve surveys conducted by the Indiana Prevention Resource Center, all surveys were conducted during a six week period in the Spring so that the high school data would be comparable to the National High School Survey data. Further surveys will be conducted during the same time period each year, in order to yield consistently valid and reliable results. Due to the relatively high rates of new drug experimentation during a particular school year, it is necessary to survey all populations at about the same time, to avoid "maturation bias." For example, results of a survey conducted in one population in September would not be comparable to results of a survey conducted in another population in April because many more students may have tried drugs for the first time during the intervening seven months.

Students complete the questionnaire in private, and anonymously deposit it in a collection box or envelope to protect confidentiality.¹ No identifying data are collected, except gender, grade in school, and ethnic background, and data are processed by a statistical team that has no direct access to the students, to assure anonymity. Students are given the option of declining to participate, or of turning in a blank survey instrument. More than 92% of eligible students complete usable surveys at every site. At each school, data collection is supervised by the classroom teachers or a classroom monitor provided by the local school. A 12-minute training videotape and written instructions are provided to all data collectors, to assure consistent collection of data. Each school has a school coordinator who is personally trained by the IPRC, and who coordinates and trouble-shoots data collection at the schools. IPRC survey staff are available via a toll-free (800) number telephone on all data collection days, in the event of questions or problems.

As a check on self reporting accuracy, students are asked how truthfully they had answered the questions. In 2002, approximately 91% answered that they were completely truthful in responding to the survey, 7.7% indicated that they were mostly truthful with their responses, and less than 1.5% responded that they were not truthful at all. Focus groups of students during the 1991 pilot test stage reported using the "mostly truthfully" option when they intended to answer all items truthfully but were uncertain about the answer to a small number of items, such as the inability to recall exact dates or numbers of drug use episodes. An error checking protocol was used to eliminate a small number of surveys that fell into three categories: (1) those in which the student replied that he/she had responded "not truthfully at all," (2) those with more than two inconsistent responses that suggested a random pattern of answers (i.e. students who report "never used" a particular drug in their lifetime, but then report use of that same drug in the past year or past month), and (3) pharmacologic implausibility (i.e. students who report such

¹ One large school corporation deviated from the prescribed protocol by removing completed surveys for repackaging and shipment. While the deviation is not likely to affect extrapolation of the findings at the state level, local-level inferences might be compromised.

excessive use of multiple drugs as to create a cumulative effect that would be lethal). These precautions eliminated surveys that were not completed seriously by the respondents. The protocols are consistent with recommended protocols to improve validity of self-reports of drug use recommended by an advisory panel on validity issues convened by the National Institute on Drug Abuse (Rouse, Kozel & Richards, 1985).

To substantiate the consistency of the self reports on the current survey, in 1992 a correlation coefficient of the reported use of various drugs on a five-point Likert scale was calculated comparing reported levels of use in the past year with use in the past month. The correlation coefficient was calculated at +0.83, which was statistically significant at $p < .01$.

The perceived risk component consisted of a seven-item belief subscale related to perceived risk of physical or other harm from drug use. The items were placed on a four point Likert format ranging from "no risk" to "great risk." This subscale was found to be internally consistent with an alpha reliability coefficient of 0.85. Reported frequency of episodes of adverse consequences of the use of alcohol and other drugs was measured on a ten-item Likert-type scale asking students to report the frequency of use-related events such as hangovers, missed school, or poor performance on a test. This subscale also was found to be internally consistent with an alpha reliability coefficient of 0.90. The subscale on perceived peer approval/disapproval consisted of seven items with approve/disapprove alternatives. The items in this subscale were internally consistent with an alpha reliability coefficient of 0.82.

The instrument was designed to produce data that are comparable with that produced by two national surveys: the "National High School Survey" and the "National Household Survey."

The "National High School Survey," also known as the *Monitoring the Future* Survey has been administered every year since 1975 to between 15,000 and 18,000 graduating high school seniors annually from approximately 150 high schools nationwide. Beginning with 1991, this survey also gathered limited data from 8th and 10th grade students in the same school corporations. It is administered through the University of Michigan's Institute for Social Research on behalf of the National Institute on Drug Abuse. The results used in this report's comparisons are those from approximately 45,000 8th, 10th, and 12th grade students in more than 400 schools nationwide.

Limitations and Possible Sources of Error

As in all surveys, the possibility of errors and the limitations of the survey, its instrument, and the manner in which it is distributed, must be taken into account when interpreting a survey's results. The following limitations are possible sources of such errors in regard to this survey:

Non-sampling errors: those errors which are the result(s) of recording mistakes (respondents marking the wrong answer, i.e. doesn't actually apply to them), coding errors (the machine skips or misreads a response), missing data (some respondents don't answer all the questions), and differences in respondents' interpretations of the questions and answers. These were minimized for this survey by a pre-testing conducted at Indiana University, specialized training of people who administered the survey, coding checks when completed questionnaires were scanned, and checks of quality control. Where the survey team suspects non-sampling errors, these have been noted in this report.

Sampling errors: those errors that occur from the way in which the respondents are chosen and populations are targeted. In other words, the reported current use of a particular drug may vary slightly from one sample to the next, because of the natural differences which exist in people, their location, social practices, etc. and the manner in which they are chosen to participate in the survey. For example, people in the far southern end of the state may have slightly different use rates of particular drugs than people in the extreme northwest corner of the state, and the state-wide results may not reflect an accurate picture of the drug use rates throughout the state if disproportionate numbers of people are sampled in the south relative to the northwest portion of the state. These errors were minimized by allocating the number of sites in each of the 10 geographic regions used by the Governor's Commission for a Drug-Free Indiana and by setting a minimum of 50 respondents and a maximum of 2,500 respondents at each site.

Scientists use statistical formulas to calculate an estimate of the amount of sampling error. Hundreds of such estimates would have to be made for this report, based upon the exact number of responses in each cell category. To avoid unnecessary difficulty in reading such reports, it is customary to report the **average** estimate of sampling error, recognizing that the error may be larger in cells with very small numbers of respondents.

For the youth populations, the average estimate of sampling error for this the whole population and for each grade 6 through 12 in this report is less than $\pm 1\%$, within a 95% confidence level. This means that we estimate that if the same number of respondents were sampled 100 times, using the same techniques, that in 95 or more of the 100 times, the percentages reported would be within or 1% of the percentages reported here.

In addition, the following should be taken into consideration when attempting to interpret the results presented in this report:

- self-reporting depends on accuracy of memory and honesty in answering questions.
- the sample from the National Household Survey was relatively small (about 4,000) compared to the Indiana sample of more than 77,000 for the same age group.
- those people surveyed were the ones who attended school on the day on which the survey was conducted at their location. It does not (nor does the National High School Survey) sample absentees or school dropouts, nor was it a compulsory survey. Participation in all three surveys was strictly voluntary.
- the National Household Survey uses a "household interview" technique that relies upon oral responses to questions posed by an interviewer. This technique may produce results that are not directly comparable to the "anonymous written questionnaire" techniques utilized by the IPRC survey and by the National High School Senior Survey.

NOTES:

This report contains the **Main Findings** of this survey (the gross prevalence rates). Over time, additional reports will be issued using the data collected in this survey. These specialized reports, and/or articles, will provide more detailed analysis of certain findings.

ATOD SURVEY 2003

Guide to Viewing and Interpreting Charts and Graphs

The Bar Charts are graphic illustrations of different prevalence rates.

- One chart for each grade is included in this section.
- The Y axes (i.e., vertical scale) for all bar charts are set to 100 percent, so that comparisons can be readily made across grades.

The Line Graphs are graphic illustrations of ATOD-use trends.

- Each chart depicts trends for all grades at a glance, with each grade represented by distinct hash marks.
- The Y axis (i.e., vertical scale) for each line graph varies. The scale for each graph is set to maximize the clarity of the trends.
